Objective 1 - EDA and logistic regression model

Introduction

The Global Longitudinal Study of Osteoporosis in Women (GLOW) (2005-2014) was a prospective cohort study of physician practices in the provision of prophylaxis and treatment against osteoporotic fractures. The goal of this research was to improve understanding of the risk and prevention of osteoporosis-related fractures among female residents of 10 countries who were 55 years of age and older. GLOW enrolled over 60,000 women through over 700 physicians in 10 countries, and conducted annual follow-up for up to 5 years through annual patient questionnaires.

The aim of the GLOW study was to collect uniform data to help describe the distribution of risk factors for osteoporosis-related fracture. This analysis uses one dataset from this study to try to predict a fracture using these risk factors.

Data Description

The data set provided is about predicting whether a woman with osteoporosis will have another bone fracture. Of course getting a bone fracture is somewhat circumstantial, but with this disease every day life could trigger a break if the progression of the disease is strong.

The dataset included a total of 14 variables: 3 ID variables which tell us the subject, doctor and physical location of each record, 4 continuous variables (BMI, Weight, Height, and Age), 6 categorical variables (PRIORFRAC, PREMENO, MOMFRAC, PREMEO, MOMFRAC, ARMASSIST, SMOKE, RATERISK), and the response (FRACTURE). We were unable to find a mapping the subjects with their location to understand the mix of countries represented.

We have 500 subjects in the dataset of which 33% of the subjects have/had fractures.

Missing values were not detected in dataset. Special characters were removed from column headings. What we know/don't know about the sample (500)

Exploratory Analysis

Assumptions

This is a prospective study which means it's a study over time of a group of similar individuals who differ with respect to certain factors under a study and how these factors affect rates of a certain outcome (Fracture vs No-Fracture) Linearity - Independence of errors - Based on SUB_ID(Subject ID) we confirm each record is an independent sample. Multicollinearity - Weight and BMI are highly correlated but we will remove one from the analysis.

GLOW dataset:

```
Variable Name Type
                     #Unique
     SUB ID
            integer
                     500 - Identification Code (1 - n)
   SITE ID integer
                        6 - Study Site (1 - 6)
    PHY ID integer 127 - Physician ID code (128 unique codes)
PRIORFRAC*
                       2 - History of Prior Fracture (1: No, 2: Yes)
             factor
        AGE
            integer
                      36 - Age at Enrollment (Years)
            numeric 128 - Weight at enrollment (Kilograms)
     WEIGHT
    HEIGHT
                      34 - Height at enrollment (Centimeters)
            integer
            numeric 409 - Body Mass Index (Kg/m^2)
       BMI
```

```
2 - Menopause before age 45 (1: No, 2: Yes)
 PREMENO*
             factor
                       2 - Mother had hip fracture (1: No, 2: Yes)
 MOMFRAC*
             factor
ARMASSIST*
                       2 - Arms are needed to stand from a chair (1: No, 2: Yes)
             factor
    SMOKE*
                       2 - Former or current smoker (1: No, 2: Yes)
             factor
                       3 - Self-reported risk of fracture (1: Less, 2: Same, 3: Greater)
RATERISK*
             factor
FRACSCORE
                      12 - Fracture Risk Score (Composite Risk Score)
           integer
 FRACTURE*
             factor
                       2 - Any fracture in first year (1: No, 2: Yes)
```

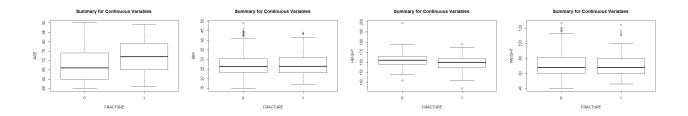

Figure 1 - Boxplots for Continuous Variables AGE, BMI, HEIGHT, WEIGHT

In Figure 1, we see the boxplots for the continous variables AGE, WEIGHT, HEIGHT, BMI.

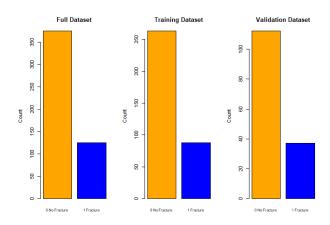

Figure 7 - Fracture Counts

Restatement of Problem and the overall approach to solve it.

Logistic regression is used to describe data and to explain the relationship between one dependent binary variable, in this case whether a woman will have a fracture related to osteoporosis, with one or more continuous or categorical variables. Using different modeling techniques, we will try to predict whether a sample will have a fracture related event.

Simple Logistic Model Selection

Model Considerations

For the purpose of feature selection for the simple logistic model, a lasso+logistic regression with cross validation (for 1000 lambda values) was performed on training data set in order to obtain the penalty value(lambda) that results in minimum misclassification rate. The result of this procedure is present in figure 7 below:

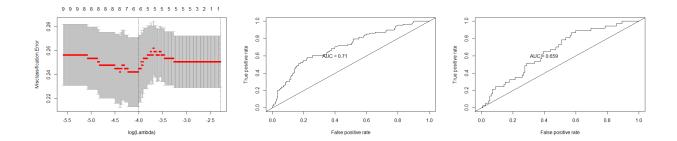

Figure 8 - Simple Logistic Regression lasso+logistic regression

Then the lasso+logistic model was rerun with best value of lambda obtained(lambda.min) from previous pr 12 x 1 sparse Matrix of class "dgCMatrix"

(Intercept) 1.52902669 trainingData.AGE 0.03598544 trainingData.WEIGHT trainingData.HEIGHT -0.03340871 trainingData.BMI trainingData.PRIORFRAC1 0.15180349 trainingData.PREMENO1 trainingData.MOMFRAC1 0.04035537 trainingData.ARMASSIST1 0.52512963 trainingData.SMOKE1 trainingData.RATERISK.L 0.33991586 trainingData.RATERISK.Q

Next, we went ahead and run simple logistic regression using this feature set of AGE, HEIGHT, PRIOR-FRAC, MOMFRAC, ARMASSIST and RATERISK.

Model Assumptions:

Assumption of binary response while running binary logistic regression.

The dependent variable is a factor with two defined levels (0 = No, 1 = Yes).

Assumption of independence among observations.

Since the method for selecting the subjects for this study and then formulation of given dataset from all of such population is not fully known, caution must be taken while generalizing the results from this analysis. Potential biases could be present among observations as selection bias, recall bias, serial and spatial correlation etc could be present. Generalizing the results from this analysis to whole population of such subjects is to be based upon assumption that subjects in given dataset are as representative of the underlying population as a random samples from such population are. For the purpose of our analysis, we assume observations in our dataset are independent of one another and proceed with the analysis.

Assumption of linearity of independent continuous predictors and their respective log odds

A scatter plot between two continuous predictors: AGE and HEIGHT as identified to be used in simple logistic model and their respective log odds is plotted and present as below.

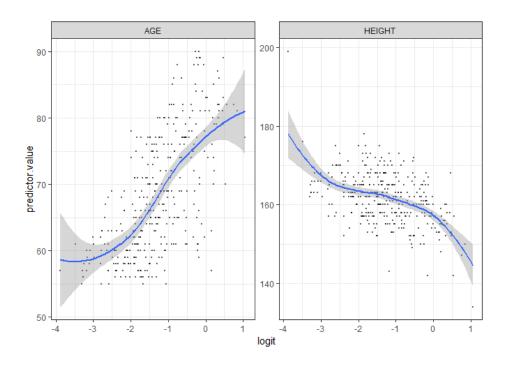

Figure 9 - Scatter Plot between AGE and HEIGHT and their log odds Simple Logistic Model Fit:

The overall logistic regression model using selected variables came out significant and found AGE, HEIGHT, ARMASSIST and RATERISK as significant predictors at alpha=0.05 level for determining probability of getting a fracture in first year(response variable). The model output is as below:

```
Call:
```

```
glm(formula = FRACTURE ~ AGE + HEIGHT + PRIORFRAC + MOMFRAC +
    ARMASSIST + RATERISK, family = binomial(link = "logit"),
    data = trainingData)

```

Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' ' 1

(Dispersion parameter for binomial family taken to be 1)

Null deviance: 395.31 on 350 degrees of freedom Residual deviance: 355.55 on 343 degrees of freedom

AIC: 371.55

A recursive model refinement process was performed by trying to add more variables that were not present in initial fit; and model performance in terms of AUC under ROC curve and accuracy via confusion matrix for validation dataset was assessed for each subsequent model. No subsequent model fit resulted in significant gains in terms of improved performance parameters. In fact, some resulted in decrease in accuracy on validation set as they were just acting as noise and didn't provide any valuable information about the response variable. Hence, initial fit was chosen as best fit and assessed further.

On the initial model fit, VIFs and influential observation analysis was then performed and results can be seen below as:

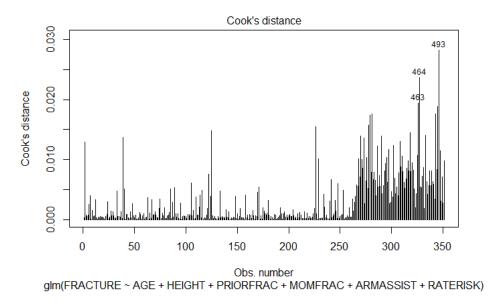

Figure 10 - Logistic Regression - Cook's D

	GVIF	\mathtt{Df}	GVIF^(1/(2*Df))
AGE	1.209972	1	1.099987
HEIGHT	1.084342	1	1.041317
${\tt PRIORFRAC}$	1.172110	1	1.082640
MOMFRAC	1.010590	1	1.005281
ARMASSIST	1.124261	1	1.060312
RATERISK	1.096380	2	1.023270

As seen from above results that multiclonality is not seen and no substantially influential observation is found as seen from Cook's d plot. Hence, we proceeded with current model for model equation formulation and coefficients interpretations.

Model Equation

```
log(\pi) = 3.33365 + 0.04347 * AGE - 0.04881 * HEIGHT + 0.22281 * PRIORFRAC + 0.33522 * MOMFRAC + 0.68418 * ARMASSIST + 0.50762 * RATERISK_2 - 0.06727 * RATERISK_3
```

Next, we converted model coefficients and their respective 95% Confidence Intervals to Normal Scale and

```

Interpretation of the Coefficients:

For AGE: All the other variables being constant, for every one-year increase in age of women, the odds of being getting a fracture in first year (versus not getting a fracture in first year) increases by a factor of 1.04(4% increase). The 95% Confidence Interval for this multiplicative factor is from 1.01(1% increase) to 1.08(8% increase).

For HEIGHT: All the other variables being constant, for every one unit increase in height of women, the odds of being getting a fracture in first year (versus not getting a fracture in first year) decreases by a factor of 0.95(5% decrease). The 95% Confidence Interval for this multiplicative factor is from 0.91(9% decrease) to 0.99(1% decrease).

** All the below coefficients are of format: The estimated odds for Person X with/without characteristic are M times the odds (of developing fracture in first year), for another Person Y without/with that characteristic.

For PRIORFRAC: All the other variables being constant, the estimated odds for a woman, who has history of prior fracture, are 1.25 (25% more) times the odds of having fracture again in first year, for a woman who didn't have prior history of fracture. The 95% Confidence Interval for this estimated odds ratio is from 0.69 times to 2.23 times.

For MOMFRAC: All the other variables being constant, the estimated odds for a woman, whose mother had hip fracture, are 1.40 (40% more) times the odds of having fracture in first year, for a woman whose mother didn't have hip fracture. The 95% Confidence Interval for this estimated odds ratio is from 0.64 times to 2.91 times.

For ARMASSIST: All the other variables being constant, the estimated odds for a woman, who needed arms to stand from a chair, are 1.98 (98% more) times the odds of having fracture in first year, for a woman who didn't need arms to stand from a chair. The 95% Confidence Interval for this estimated odds ratio is from 1.15 times to 3.43 times.

For RATERISK.2: All the other variables being constant, the estimated odds for a woman, who self-reported that her risk for developing fracture is same as others of the same age, are 1.66 (66% more) times the odds of having fracture in first year, for a woman who self-reported that her risk for developing fracture is less than others of the same age. The 95% Confidence Interval for this estimated odds ratio is from 1.03 times to 2.71 times.

For RATERISK.3: All the other variables being constant, the estimated odds for a woman, who self-reported that her risk for developing fracture is greater than others of the same age, are 0.93 (7% less) times the odds of having fracture in first year, for a woman who self-reported that her risk for developing fracture is less than others of the same age. The 95% Confidence Interval for this estimated odds ratio is from 0.61 times to 1.45 times.

Model Assessment:

Model performance was assessed on validation data using following parameters:

- 1. AUC under ROC curve
- 2. Overall Accuracy, Sensitivity and Specificity values obtained from confusion matrix.

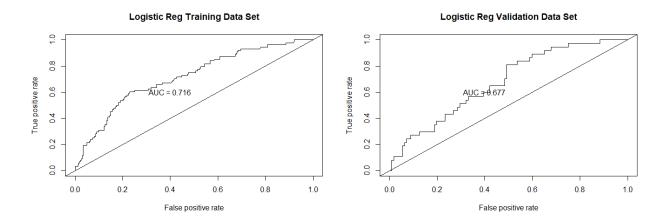

Figure 10 - Simple Logistic Regression - Performance

```

Figure 11 - Simple Logistic Regression - Confusion Matrix

As seen from above ROC curves and confusion matrix:

- 1. Training set AUC is 71.6% and that for validation data set is about 67.7%. This is understandable since model was created using data training data set.
- 2. Overall Accuracy of the model is at 74.5% with high sensitivity 94.64% but very low specificity 13.51%.
- 3. There relative low values of overall AUC and accuracy could be due to:
 - a. Lack of complexity in the current model (in terms of higher order terms, transformations, interactions) etc.
 - b. The available feature set and number of samples available are not sufficient enough to accurate model most of the trends in actual population data.
 - c. Class imbalance that is present in original, training and validation data set. Especially, the number of true positive cases are very much under represented in both the training and test datasets and this could be the cause of low specificity values obtained from this model.
- 4. Specificity for the model could be improved by lower the cutoff for classification from its initial value of 0.5. This should be warranted since cost of not predicting true positive outweighs cost of predicting false positive in the current situation.

Final conclusions from the analysis of Objective 1

To improve the accuracy and AUC for the model, we would next increase complexity in current model by adding interactions to it.

Objective 2 - Additional Competing Models

• The performance of the Simple Logistic Regression model developed earlier has performance characteristics described in Figure X and Figure X with the AUC under ROC curve and Confusion Matrix.

Logistic Regression Model with Interactions

Model Considerations:

Since simple model was lacking in terms of complexity, hence interaction terms were added to the initial simple model in the hope of improving its predictive capability. After the recursive EDA process, three potential interactions were found from the dataset: AGE * PRIORFRAC, MOMFRAC * ARMASSIST and AGE * RATERISK. These could improve model performance as seen from below graphs that distribution for AGE variable among PRIOR FRAC groups is different for FRACTURE and NON-FRACTURE group and same is observed for MOMFRAC and ARMASSIST for levels of FRACTURE group as seen below:

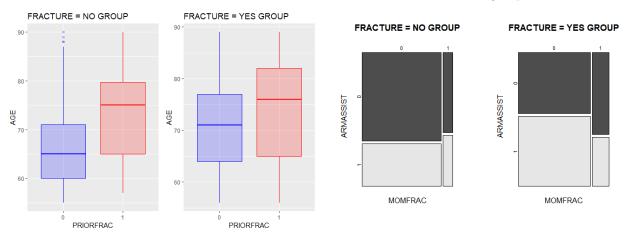

Figure 12 - Logistic Regression - Interactions

Model Assumptions:

Model assumptions are satisfied as we have seen from assumption section in simple logistic model section.

Model Fit:

The overall logistic regression model using selected variables and interactions came out significant. But, since interactions were added, multicollinearity is created and VIF for the model increased as seen below:

	GVIF	Df	GVIF^(1/(2*Df))
AGE	1.997142	1	1.413203
HEIGHT	1.102446	1	1.049975
PRIORFRAC	67.052577	1	8.188564
MOMFRAC	1.872604	1	1.368431
ARMASSIST	1.292878	1	1.137048
RATERISK	4440.469420	2	8.163140
AGE:PRIORFRAC	71.017561	1	8.427192
AGE:RATERISK	4423.340582	2	8.155256
MOMFRAC: ARMASSIST	2.037634	1	1.427457

This issue was dealt by centering the AGE variable and re-running the model. The VIFs came back to normal values after centering on AGE variable was performed as seen below from VIFs after centering:

AGE	1.997142	1	1.413203
HEIGHT	1.102446	1	1.049975
PRIORFRAC	1.293722	1	1.137419
MOMFRAC	1.872604	1	1.368431
ARMASSIST	1.292878	1	1.137048
RATERISK	1.354533	2	1.078816
AGE:PRIORFRAC	2.076106	1	1.440870
AGE:RATERISK	1.295266	2	1.066816
MOMFRAC: ARMASSIST	2.037634	1	1.427457

The model output is as below:

Deviance Residuals:

```
Min 1Q Median 3Q Max
-1.5521 -0.7592 -0.5543 0.2845 2.3802
```

Coefficients:

AGE:RATERISK.Q	0.14622	0.22380	0.653	0.51355	
MOMFRAC1:ARMASSIST1	-0.74229	0.76220	-0.974	0.33011	

Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' '1

(Dispersion parameter for binomial family taken to be 1)

Although no interaction was significant at alpha=0.05 level, interaction between AGE*PriorFrac looks promising (p-value = 0.10688). Hence, using the above model for model equation formulation.

Model Equation:

Model Assessment.

Model performance was assessed on validation data using following parameters:

- 1. AUC under ROC curve
- 2. Overall Accuracy, Sensitivity and Specificity values obtained from confusion matrix.

Figure 14 - Logistic Regression with Interactions - Confusion Matrix

As seen from above ROC curves and confusion matrix:

- 1. Training set AUC is 72.5% and that for validation data set is about 72.2%. This is understandable since model was created using data training data set.
- 2. Overall Accuracy of the model is at 75.17% with high sensitivity 93.75% but low specificity 18.92%.
- 3. This model performed little better over simple model with AUC increasing from 67.7% to 72.2% and overall accuracy increasing from 74.5% to 75.17%.
- 4. These slight increases in accuracy are consistent with the outcome received from model fit that none of

the interactions added were highly significant. So, added complexity did increase the overall AUC by about 5% but was not improved performance significantly.

- 5. There relative low values of overall AUC and accuracy could be due to:
- a. Still Missing complexity in the current model (in terms of higher order terms, transformations, further interactions) etc. b. The available feature set and number of samples available are not sufficient enough to accurate model most of the trends in actual population data.
- c. Class imbalance that is present in original, training and validation data set. Especially, the number of true positive cases are very much underrepresented in both the training and test datasets and this could be the cause of low specificity values obtained from this model.
- 6. Specificity for the model could be improved by lower the cutoff for classification from its initial value of 0.5. This should be warranted since cost of not predicting true positive outweighs cost of predicting false positive in the current situation.

Random Forest and Conditional Random Forest Models

Model Considerations.

To further account for the remaining complexity and improve model predictive ability, we ran the ensemble based random forest model. We ran both flavors of random forest model that is normal one and conditional random forest one. Normal random forest model is biased towards predictors with more levels since knowing these would decrease the entropy the most and provide more information. Hence, normal random forest favors predictors with more levels. Whereas, conditional random forest takes this into account and produce more unbiased trees than normal random forest by assigning more weights to certain nodes at the time of aggregation.

A recursive process was performed to tune the random forest model for ntee, mtry and maxnodes parameters. Without pruning the tree length, random forest overfitted on our relatively small training data set but performed poorly as compared to logistic regression on validation data set as seen below:

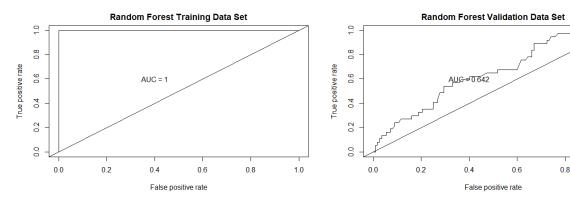

Figure 15 - Random Forests - Performance

Maxnodes parameter along with ntree and mtry parameters was adjusted so as to achieve better performance and then we proceeded with fitting the random forest model.

Model Assumptions:

Since random forest is a non-parametric test which relies upon ensemble techniques, it doesn't require model assumptions to be satisfied before running the model.

Model Fit.

Call:

1.0

Figure 18 - Conditional Random Forest Confusion Matrix

As seen from above ROC curves and confusion matrix: 1. Random Forest model improves on overall AUC performance slightly and takes it to 74.2% as compared to logistic regression with interaction model that had 72.5% AUC. So it did model some extra remaining complexity.

- 2. This model performed really badly as compared to other models in classifying true positives and have specificity value of zero.
- 3. This could be due to the fact that our training and test datasets have slight proportion of positive cases and model is unable to capture trends in positive observations as accurately as it captured for negative observations. Small sample sizes in training and validation sets and class unbalance is appearing to contribute to this discrepancy, since random forest model is prone to overfitting when sample sizes are relatively small.
- 4. Conditional random forest model performed better than this model in terms of overall accuracy and specificity values as seen from below results but it suffered on overall AUC. But again, this could be caused due to random variation and biases in data sets.

Linear Discriminant Analysis Model

Model Considerations.

LDA can only be done with continuous predictors and in our dataset we have only four continuous predictors: AGE, HEIGHT, WEIGHT and BMI. As we have seen in EDA part that categorical variables appear to be significant in classifying the response, throwing away the information they provide could result in decrease in overall performance of the model (and BMI and WEIGHT not been so significant as seen from logistic model) as compared to rest of the models.

Model Assumptions:

Assumption of Equal Variance / CoVariance.

We computed the amount of the between-group variance that is explained by each linear discriminate. In this dataset, we tested whether the variance in each continuous variable is the same for all subjects with/without Fractures.

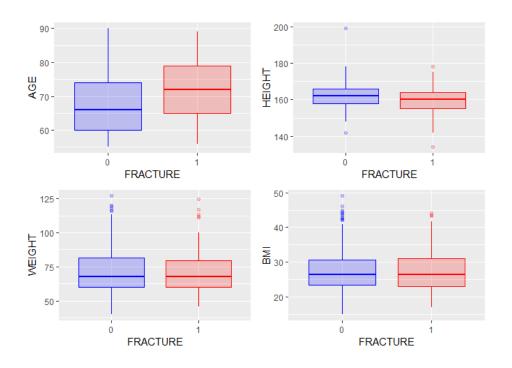

Figure 20 - LDA Equal Variance

```

Levene's Test for Homogeneity of Variance (center = median)
       Df F value Pr(>F)
group
       1 0.9475 0.3308
      498
Levene's Test for Homogeneity of Variance (center = median)
       Df F value Pr(>F)
group 1 0.0188 0.8911
```

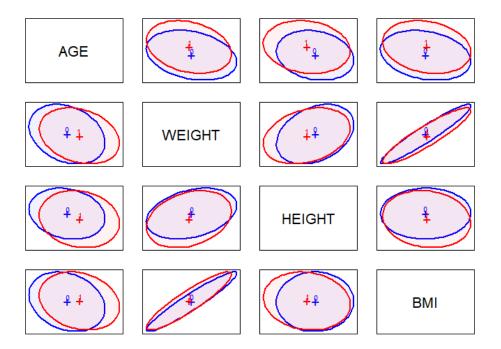

Figure 21 - LDA Ellipse Plots

From the boxplots and ellipse plots above we can didn't observe difference in spread of eclipses and axis of eclipses are fairly aligned for each pair. We also ran a Levene's Test between each predictor and response and result confirms that spread for each predictor is not differing for levels of response

Assumption of independence among observations.

Since the method for selecting the subjects for this study and then formulation of given dataset from all of such population is not fully known, caution must be taken while generalizing the results from this analysis. Potential biases could be present among observations as selection bias, recall bias, serial and spatial correlation etc could be present. Generalizing the results from this analysis to whole population of such subjects is to be based upon assumption that subjects in given dataset are as representative of the underlying population as a random samples from such population are. For the purpose of our analysis, we assume observations in our dataset are independent of one another and proceed with the analysis.

Assumption of Normality

Density plots were plotted for each predictor for both levels of response as seen below:

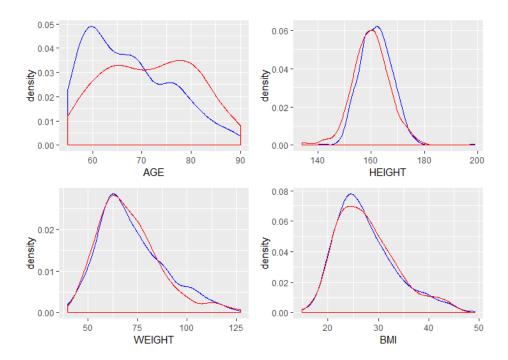

Figure 22 - LDA Density Plots

Distribution of all predictors except AGE looks sufficiently normal and have about similar spread. To check on AGE variable a QQ Plot for AGE for both levels of response variable was plotted as seen below:

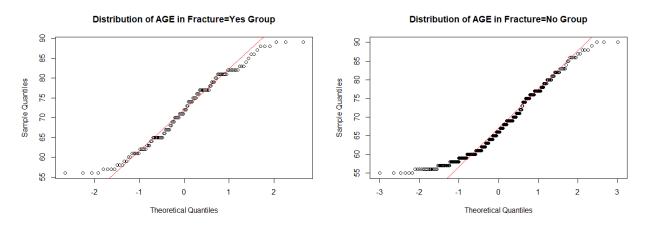

Figure 23 - LDA QQ Plots

As seen from the above QQ plots and presence of sufficient sample size, distribution of AGE looks sufficiently Normal for both levels of response variable.

Since all the assumptions for LDA have been met, we would now go ahead and run the LDA model.

Model Fit.

Call: lda(FRACTURE ~ AGE + HEIGHT + WEIGHT + BMI, data=trainingData)

Prior probabilities of groups:

Figure 25 - LDA Confusion Matrix

As seen from above ROC curves and confusion matrix:

- 1. Training set AUC is 67% and that for validation data set is about 60.2%. This is understandable since model was created using data training data set.
- 2. Overall Accuracy of the model is at 73.15% with high sensitivity 94.64% but very low specificity 8.1 %.
- 3. There relative low values of overall AUC and accuracy could be due to:
- a. Lack of complexity in the current model (in terms of higher order terms, transformations, interactions) etc.
- b. The fact tha LDA only assess continuous variables.
- c. Class imbalance that is present in original, training and validation data set. Especially, the number of true positive cases are very much under represented in both the training and test datasets and this could be the cause of low specificity values obtained from this model.
- 4. Specificity for the model could be improved by lower the cutoff for classification from its initial value of 0.5. This should be warranted since cost of not predicting true positive outweighs cost of predicting false positive in the current situation.

To improve the accuracy and AUC for the model, we would need increase the number of continuous variables to explain the dataset.

Note on PCA

Our dataset had only 4 continuous predictors so PCA would not help us much in terms of dimensionality reduction. We ran initial PCA model to see if data separates out well. But as seen from below output from Scree plot that 4 Principal Components were required to explain all variance and that's equal to number of predictors used. Also, data didn't separate out well between PC1 and PC2.

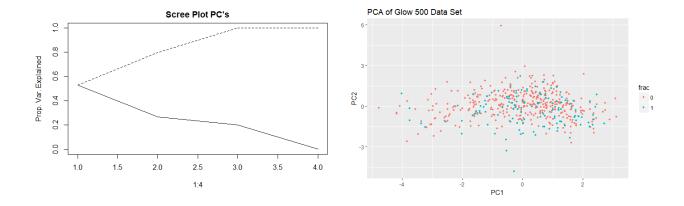

Figure 26 - LDA PCA Notes

"

Summary table of performance

Model	Predictors	Accura	cy95% CI	Sensitivi	ty Specificity	AUC
Logistic Regression (logit)	7	74.5%	(66.7%, 81.3%)	94.6%	13.5%	67.8%
Logistic Regression w/Interactions (logit)	7+3 interactions	75.2%	(67.4%, 81.9%)	92.9%	21.6%	72.2%
Random Forest*	10	74.5%	(66.7%, 81.3%)	99.1%	0.0%	74.2%
*RF Lower Cutoff (decreasing the probability from 50% to 30%)	10	73.8%	(66%, 80.7%)	91.1%	21.6%	
Conditional Random Forest	10	75.2%	(67.4%, 81.9%)	94.6%	16.2%	69.3%
LDA	4	73.2%	(65.3%, 80.1%)	94.6%	8.1%	60.2%

Conclusion/Discussion

In summary, as seen from above table with performance metrices:

Simple logistic model suffers in terms of prediction accuracy since its not complex enough to model all trends present in dataset. Logistic regression model with interactions added did a better job in improving the overall AUC and accuracy over the simple logistic model. Random Forest increased the overall AUC but performed really badly in terms of specificity and looks to overfit the trends in dataset on true negative side and hence predicting badly on true positive side since our training/validation dataset was unbalanced in favor of true negative observations. LDA, as expected performed poorly as compared to other models in terms of overall AUC since it didn't consider categorical variables and it can be seen from EDA that most of categorical variables looked promising for separating the response. And also, two of continuous predictors: Weight and BMI were not significant as seen by the logistic model fit. Hence, all in all, in our given dataset, we think logistic model with interactions performed better than rest of the models since it didn't overfit on true negative side and had enough complexity as compared to rest of the models to make informed predictions.

Data Set 1: Osteoporosis in Women

From Hosmer, Lemeshow, and Sturdivant (2013), Applied Logistic Regression, 3rd Edition. The Global Longitudinal Study of Osteoporosis in Women (GLOW) is an international study of osteoporosis in women aged 55 years and over. The major goals of the study are to examine prevention and treatment of fractures and distribution of risk factors among older women. Complete details on the study as well as a list of GLOW publications may be found at the Center for Outcomes Research web site, http://www.outcomes-umassmed.org/glow. There are over 60K observations in the original data set. This data set contains a sample of 500 of them. The link below is to a website with the data set and description of the variables. The data set in question is called "glow500".

https://www.umass.edu/statdata/statdata/glow/index.html Note: If you choose this data set, you MAY NOT use the Hosmer, Lemeshow, and Sturdivant text to help you in your analysis. You may only use Chapter 1 in order to obtain a description of the data.

Of course if you dont have the book

https://www.umass.edu/statdata/statdata/data/glow/glow.pdf provides definitions to the variables.

The Global Longitudinal Study of Osteoporosis in Women (GLOW) (2005-2014) was a prospective cohort study of physician practices in the provision of prophylaxis and treatment against osteoporotic fractures. The goal of this research was to improve understanding of the risk and prevention of osteoporosis-related fractures among female residents of 10 countries who were 55 years of age and older. GLOW enrolled over 60,000 women through over 700 physicians in 10 countries, and conducted annual follow-up for up to 5 years through annual patient questionnaires.

Setup:

Data Import and Cleaning

Missing values were not detected in dataset. Special characters were removed from column headings. What we know/don't know about the sample (500): 1. We do not know if the subjects are distributed equally around the world. We will assume that the same percentage from each region was selected for the sample in this dataset. 2. Based on the Sub_ID(Subject ID), we can assume that the datat is independent sample of participants.

Correlations

BMI and Weight show to be highly correlation which makes sense since weight is a factor in calculation of BMI. We will remove Weight from models in order to meet assumptions.

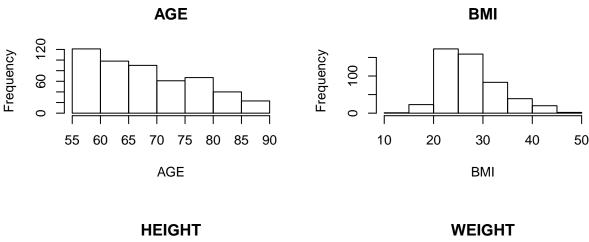

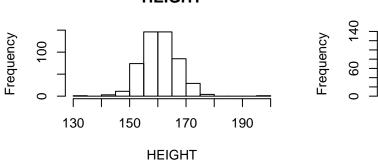

Visualization of Continuous Variables For the categorical variables, we show an unbalanced dataset of subjects with majority false PRIORFRAC, PREMENO, MOMFRAC, ARMASSIST, and SMOKE. There was a good balance of subjects in the 3 levels of RATERISK. An unblanced dataset will cause a model to favor the skewed numbers.

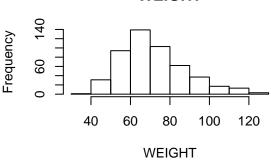

For the continous variables, we can see that BMI and Weight are highly correlated and weight and height are also correlated. When building the model, we will remove Weight as to meet the assumptions of logistic regression.

```
# Data visualizations
dataset_numeric = numericVar

#Histograms
par(mfrow=c(2,2))
for (i in 1:4) {
   hist(dataset_numeric[,i],xlab=names(dataset_numeric)[i],main=names(dataset_numeric)[i])
}
```

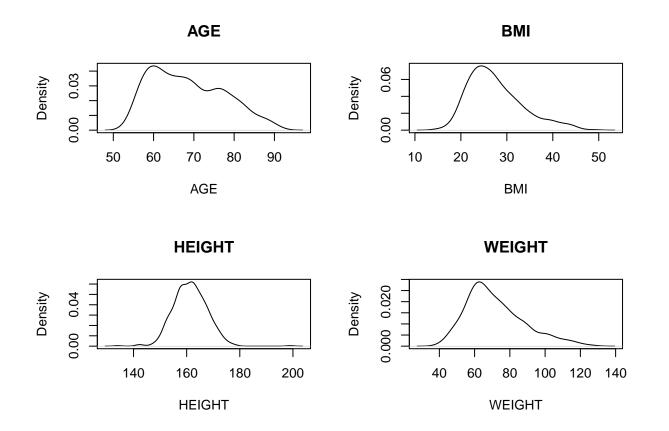

In the full dataset we have a majority of subjects are younger. The range of ages is between 55-90.

About 300 out of 500 subjects are in the 20-30 BMI score range.

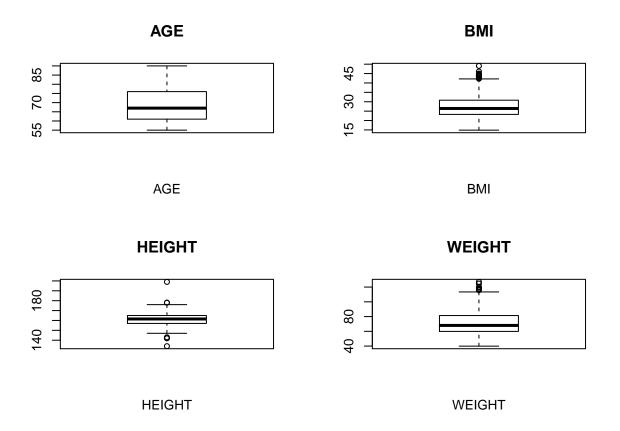

Majority of subjects landed between 150 and 180 inches in height.

We show a majority of subjects are in the weight range of 60-80.

```
#Density Plots
par(mfrow=c(2,2))
for(i in 1:4) {
    plot(density(dataset_numeric[,i]), xlab=names(dataset_numeric)[i], main=names(dataset_numeric)[i])
}
```

Checking the Balance of the Full dataset

The current sample dataset containes a larger proportion of subjects that did not develop fracture. Building a model against this dataset could produce bias towards the majority class. Below you will see how many subjects with(1)/without(0) Fractures as well as the proportion percentage for each. After splitting the dataset into training and validation(test) sets, we noticed the proportion of the training and test was not any better.

We fit a logistic model on the unbalanced training dataset with a threshold of .05. It shows a Precision of 1 which says there are no false positives. Recall equals 0.20 is low and indicates that we have higher number of false negatives. The F equals 0.20 is also low and suggests weak accuracy of this model.

We also plotted a ROC curve to visualize the model. The AUC equals 0.764 which is low and shows the data is not balanced.

We will attempt to balance the dataset in order to create a more balanced distribution of and a better prediction.

```

ROC curve

Area under the curve (AUC): 0.760

##Create a vector of all categorical variables and run frequency 2X2s with Mosaic plots.

Chi-Square Test For the 2-way tables the chisq test independence will show if 2 categorical variables are related in some population. Null Hypothesis: The two categorical variables are independent. Alternative Hypothesis: The two categorical variables are dependent

Variable: PRIORFRAC 41% of subjects with Prior Franctures also had current Fractures but only make up 25% of the overall subjects in the sample that had prior fractures. The Chi-squared p-value favors overwhemingly the alternative hypothesis that the PRIORFRAC variable is dependent on Fracture variable.

Variable: PREMENO 80% of the sample subjects are not in Pre-Menopausehad of which 24% had fractures. The same frequency of 25% Premenopausal women had fractures. The Chi-squared p-value favors the null hypothesis that the PREMENO variable is independent on Fracture variable.

Variable: MOMFRAC 13% of subjects have Mothers with a history of fractures. Out of those 13%, 36% of subjects also had fractures. The Chi-squared p-value favors the alternative hypothesis that the MOMFRAC variable is probably dependent on Fracture variable.

Variable: ARMASSIST 62% (312/500) subjects do not have Armassist of which 20% had fractures. Of those with Armassist, 33% had fractures. The Chi-squared p-value favors the alternative hypothesis that the ARMASSIST variable is most likely dependent on Fracture variable.

Variable: SMOKE In the dataset, 93% of subjects are non-smokers of which 26% had fractures. 7% of the subjects who were smokers of which 26% had no fractures. Although the subjects are not balance in smoker vs non-smoker category, the p-value for Chi-squared test shows .47 we favor the alternative hypothesis that the Smoke variable is dependent on the Fracture.

Variable: RATERISK Raterisk shows the frequency of subjects in each Raterisk level is between 29%-33%. This is pretty even in terms of how many subjects are within each Raterisk. For those that did have Fractures, their probability of a fracture increased with the level of Raterisk. This makes sense.

FRACTURE vs RATERISK

Logistic Regression

Training set will be 70% of dataset and Test set will be remaining 30%

Build Model using Training Data

Question of Interest? What are the odds of getting a fracture, given certain conditions?

```
set.seed(84)
model <- glm(FRACTURE ~ AGE + WEIGHT + HEIGHT + BMI + PRIORFRAC + PREMENO + MOMFRAC + ARMASSIST + SMOKE
model
##
  Call: glm(formula = FRACTURE ~ AGE + WEIGHT + HEIGHT + BMI + PRIORFRAC +
##
##
       PREMENO + MOMFRAC + ARMASSIST + SMOKE + RATERISK, family = "binomial",
       data = trainingData)
##
##
